### ABSTRACT

New and interesting occurrences of filamentous green and red algae were observed in samples collected from two urban eutrophic ponds (Lago Moinhos de Vento and Lago Chinês) in Porto Alegre, Rio Grande do Sul State, Southern Brazil, namely *Pithophora oedogonia* (Montagne) Wittrock, *Spirogyra reinhardii* Chmielevski, and “*Audouinella macrospora*” (the ‘Chantransia’ stage of *Batrachospermum*). *Spirogyra reinhardii* is recorded for the first time for the city of Porto Alegre. *Pithophora oedogonia* is new to Brazil. Cellular measurements, illustrations, and biogeographical distribution of both species are given, as well as pictures of the ‘Chantransia’ stage of *Batrachospermum*.

**Key words:** *Pithophora*, *Spirogyra*, ‘Chantransia’ stage, eutrophic ponds, Brazilian subtropics.

### RESUMO

**Algumas ocorrências interessantes de algas filamentosas de água doce em Porto Alegre, Rio Grande do Sul, Brasil**

Algumas ocorrências interessantes de algas filamentosas verdes e vermelha foram observadas em amostras coletadas em dois lagos artificiais (lago Moinhos de Vento e lago Chinês) de Porto Alegre, Rio Grande do Sul, a saber: *Pithophora oedogonia* (Montagne) Wittrock, *Spirogyra reinhardii* Chmielevski e “*Audouinella macrospora*” (fase ‘Chantransia’ de *Batrachospermum*). *Spirogyra reinhardii* é citada pela primeira vez para a cidade de Porto Alegre. *Pithophora oedogonia* é citação nova para o Brasil. Neste trabalho, são apresentadas medidas celulares, ilustrações e distribuição geográfica das duas espécies, bem como fotomicrografias da fase ‘Chantransia’ de *Batrachospermum*.

**Palavras-chave:** *Pithophora*, *Spirogyra*, fase ‘Chantransia’, citações novas.

### INTRODUCTION

The first studies on the freshwater algae of Porto Alegre, Southern Brazil, were published by Bohlin (1897) and by Borge (1903a, 1903b) from samples collected by Dr. G. Malme, during the “Ersten Regnellschen Expedition”, which have reported 73 taxa of green algae in the region. Only many years later, Flores (1972) published a list with 27 genera of

green algae from a pond located in Parque Farroupilha. From 1972 until now, other authors have studied algal genera and species collected from different sampling sites in the city, and some papers were published (see Franceschini, 1992; Torgan et al., 1999, 2001, 2003).

In 1992, a study on planktonic and periphytic algae from the urban zone of Porto Alegre and environs was published by Franceschini. Ninety-six samples collected in six localities, from April 1986 to January

Recebido em: 01.08.2005; aceito em: 26.01.2006.

1987, revealed a rich algal flora: 378 taxa of cyanobacteria, red algae, euglenoids, dinoflagellates, green algae, and ochrophytes (excepting the diatoms) were identified; among them, green algae was the richest group, including 228 species, varieties, and formae.

Periodically, algal samples have been collected in some of these same sites by undergraduate and graduate students in courses on the algae and freshwater ecology, as well as by researchers and professionals in these fields.

In October 2004, we have observed new and interesting occurrences of filamentous green and red algae in two of these sampling sites, namely Lago Moinhos de Vento and Lago Chinês. In order to increase the knowledge on the algal composition in Brazilian subtropics, cellular measurements, illustrations and biogeographical distribution of two species of green algae, as well as pictures of a red alga from eutrophic ponds, are given in this paper.

## MATERIALS AND METHODS

Porto Alegre is the capital of Rio Grande do Sul State. It is located at 30°01'53" S and 51°13'19" W, in the south-eastern region of Brazil. The climate is subtropical humid (Cfa type, according to Köppen's classification), with annual mean temperature about 18°C. In summer, the mean temperature of the hottest month (January) is higher than 22°C. In winter, the mean temperature of the coldest month (July) is about 13°C. The annual average rainfall varies from 1250 to 1500 mm, with well distributed rains along the year (Livi, 1998; Nimer, 1990).

The sampling sites are situated in the urban zone, namely: Lago Moinhos de Vento (Fig. 1A; area 3300 m<sup>2</sup> and maximum depth about 1.5 m) and Lago Chinês (Fig. 1B; area 1000 m<sup>2</sup> and maximum depth about 0.50 m). Maps of the area and more details of the sampling stations are given by Franceschini (1992).

During the microscope analyses, we have observed a relative abundance of Sphaeroplaeales (e.g. *Coelastrum*, *Scenedesmus*, and *Pediastrum*) in the plankton of the alkaline waters of Lago Moinhos de Vento. Many macrophytes present in the slightly acidic waters of Lago Chinês have favoured the development of desmids (e.g. *Closterium*, *Cosmarium*, *Micrasterias*, and *Pleurotaenium*) in the metaphyton of this pond.

Samples were taken in spring (14.X.2004). They were collected on the shores of the two localities

(see Fig. 1A, B). Submerged stems and leaves of macrophytes covered by an abundant algal mucilage, as well as filamentous algae were collected and put in glass bottles filled with water. The material was taken alive to the laboratory of the Department of Botany, Rio Grande do Sul University (UFRGS), and then preserved in 5% formalin.

In the field, water surface temperature and pH were measured with a Hanna HI 8314 combined electronic meter. In 15.XII.2004, we have returned to the sites for measuring the transparency with a Secchi disk 0.20 m diam., and the shore depth with a ruler.

Drawings and measurements of the algal species were made with a light microscope Wild M20 equipped with a camera lucida. Photomicrographs of the algae were made with a digital camera Canon A510.

All samples are kept at the Herbarium ICN of the Department of Botany, Rio Grande do Sul University.

## RESULTS AND DISCUSSION

Table 1 summarises the measurements of water surface temperature, pH, transparency and depth on the shores of the two ponds, as well as the occurrence of the algae in each one.

### Green algae

#### Class Ulvophyceae

##### *Pithophora oedogonia* (Montagne) Wittrock

(Fig. 2-17, 24, 25)

Vegetative cells 785-980 µm long, 60-70 µm width; apical akinetes 150-225 µm long, 70-90 µm width; intersperse akinetes 120-195 µm long, 75-90 µm width.

**Remarks:** This species was found in the slightly acidic waters of Lago Chinês (Tab. 1), forming free-floating mats on the shores.

*Pithophora sumatrana* is the only species mentioned by Schmidle (1901) to Brazil (see Bicudo & Menezes, 2005, p. 180). Rosa et al. (1974) have only mentioned the genus *Pithophora* in the results of a survey on algal genera from several ponds at Parque Farroupilha (where Lago Chinês is located) and Parque Paulo Gama, in Porto Alegre. Thus, *Pithophora oedogonia* is new to the country.

**Biogeographical distribution:** *Pithophora oedogonia* and the other species of the genus have been reported as very common in ponds from tropical regions and

during summer in temperate regions (Bourrelly, 1990; Bourrelly & Manguin, 1952; Graham & Wilcox, 2000; O'Neal et al., 1985).

### Class Zygnematophyceae

#### *Spirogyra reinhardii* Chmielevski

(Fig. 18-23, 26, 27)

Vegetative cells 70-145 µm long, 110-120 µm width; zygosores ovoid (sometimes nearly globose) 110-150 µm long, 80-100 µm width, outer spore wall colourless and smooth, middle spore wall brown.

**Remarks:** Many filaments were observed forming mucilaginous masses on the shores of Lago Chinês (Tab. 1).

A long time ago, Borge (1903b) reported *Spirogyra reinhardii* to an unknown locality in the physiographic region of Depressão Central, centre of Rio Grande do Sul State. This taxon is now being described for the first time to the city of Porto Alegre. We have no additional information on the occurrence of this species in another locality in Brazil.

**Biogeographical distribution:** *Spirogyra reinhardii* has been found in Africa, Europe and South America (Gauthier-Lièvre, 1965; Palamar-Mordvintseva & Schyndanovina, 2000; Tell, 1985).

### Red alga

#### Class Florideophyceae

#### 'Chantransia' stage of *Batrachospermum*

(Fig. 28, 29)

**Remarks:** This alga was found on macrophytes (e.g. stems of Poaceae) inhabiting the shores of both ponds (Tab. 1).

According to Necchi et al. (1993a, 1993b) and Necchi & Zucchi (1995, 1997), the 'Chantransia' stage of members of Batrachospermales can be misinterpreted as species of *Audouinella*, which is an additional problem in identifying some taxa of freshwater red algae. By its morphological and morphometric characters, our material was first identified as *Audouinella macrospora* (Wood) Sheath et Burkholder. However, Necchi & Zucchi (1997) have demonstrated that *A. macrospora* is not a good species; instead, it is a complex involving the 'Cantransia' stage of several species of *Batrachospermum* and probably of other members of the Batrachospermales (e.g. *Lemanea*, *Paralemanea*, and *Thorea*).

Baptista & Saalfeld (1974) have collected the genus *Batrachospermum* in clean flowing waters from different localities of Rio Grande do Sul State, including Porto Alegre, but no indication of sampling sites were given. Data obtained from literature report *Batrachospermum* as a freshwater alga occurring in well-aerated, running streams, and also in spring-fed ponds, bogs or lakes around the world (Bourrelly, 1985; Graham & Wilcox, 2000; Lee, 1992; Necchi, 1990). Our specimens of 'Chantransia' were found in both ponds for the first time, so it is interesting to remark its occurrence in the eutrophic waters of Lago Moinhos de Vento and Lago Chinês.

Kristiansen (1996) has given an interesting review on the various methods for dispersal of freshwater algae, and has considered four main types, *viz.* airborne dispersal, by water, by organisms (e.g. beetles, dragonflies, birds, and mammals), and by man. As regards the human recent importance in algal dispersal, "even the energetic field naturalist may be unconsciously responsible for extending the range of a species, as he empties the residues of his collections of the day into some convenient puddle or stream" (Carpenter apud Talling, 1951). At present, we have no available information for any conclusive discussion on the occurrence of a red alga in an unusual habitat, such as eutrophic ponds from the urban zone of Porto Alegre. Much research is necessary to enlarge the knowledge on the ecological preferences of this alga.

### CONCLUSIONS

Samples collected during spring from two urban eutrophic ponds in Porto Alegre, subtropical southeastern region of Brazil, revealed new and interesting occurrences of filamentous green and red algae.

Among the green algae, *Pithophora oedogonia*, a species found mainly in tropical regions, is new to Brazil; *Spirogyra reinhardii*, which has a scattered distribution, is being reported for the first time to the city of Porto Alegre, many years after it was first cited to an unknown locality of Rio Grande do Sul State.

"*Audouinella macrospora*", which is the 'Chantransia' stage of the red alga *Batrachospermum*, was found in both eutrophic ponds, that is, in an unusual habitat since *Batrachospermum* species occur preferably in clean running waters.

These finds incite us to much more work, including sampling during different seasons of several years, and analyses of environmental variables, to know better the ecological preferences of these algae.

## ACKNOWLEDGEMENTS

The authors thank Dr. Rosa T. Guerrero and Dr. Albano Schwarzbold for their help, respectively, in laboratory and field analyses, Dr. Maria Luisa Lorscheitter, Dr. Lezilda Carvalho Torgan and Dilma Nascente for their help with the bibliography, Maewe de Assis Brasil and Jon Jeffrey Davison for revising the English.
